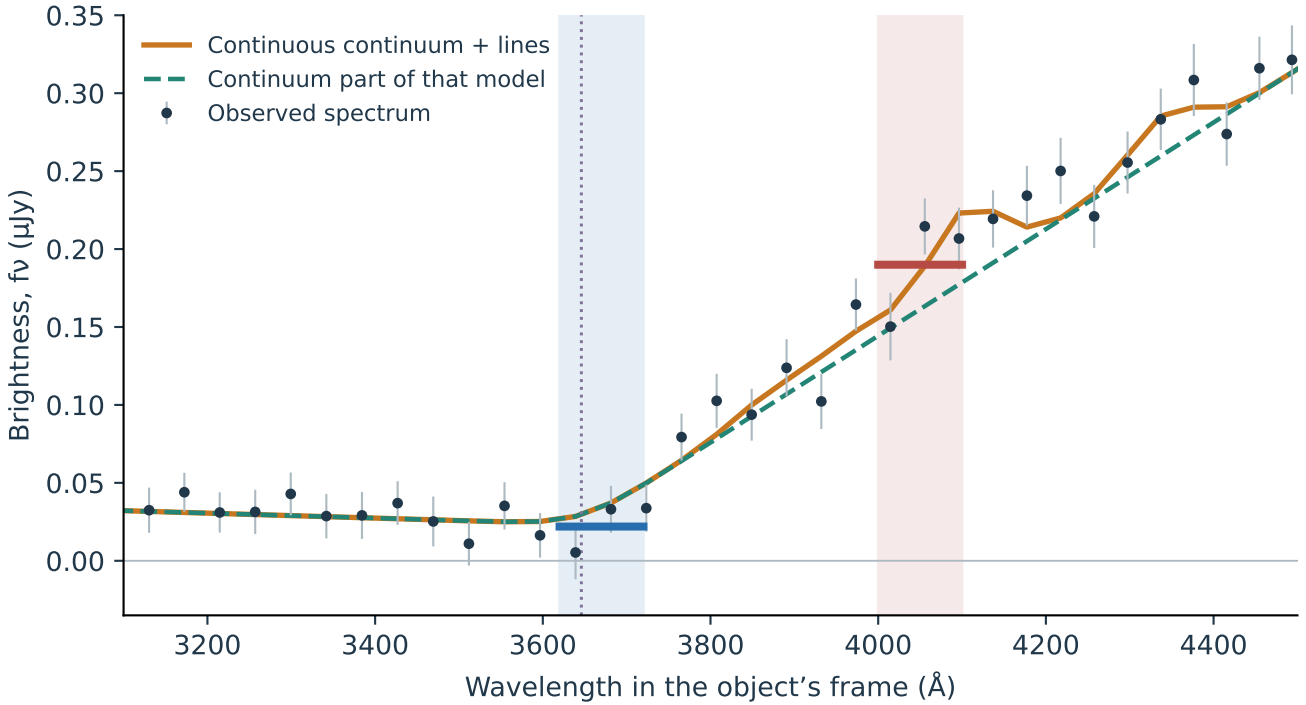
A large contrast can have an uncertain explanation

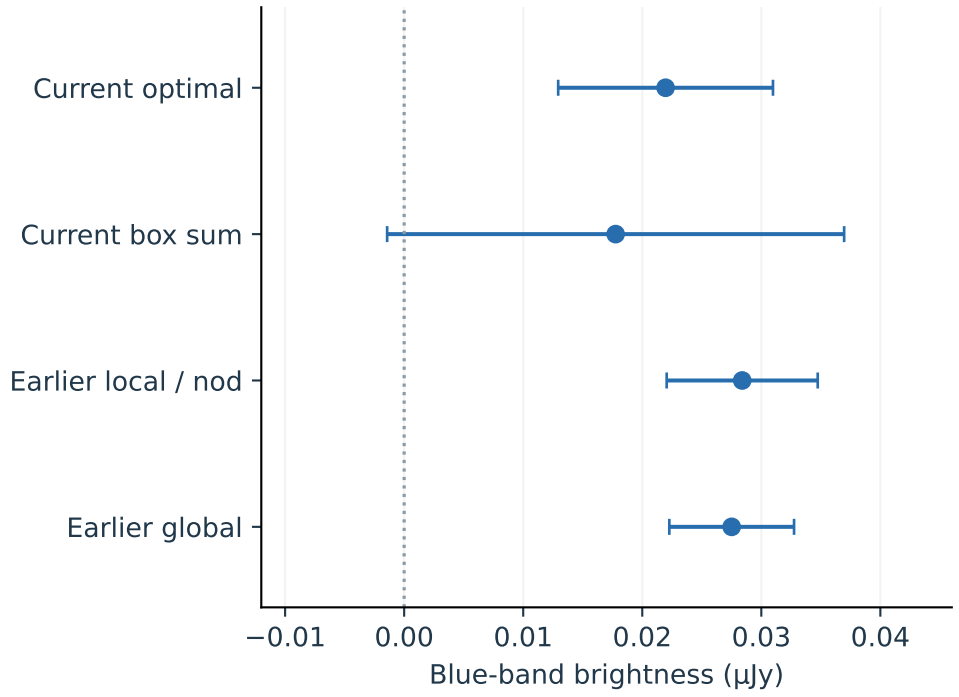
THE CLIFF · The same JWST observations, examined two ways

Frozen band ratio: 8.65 · Allowing a jump improves the illustrative fit's χ^2 by only 0.065*

A · A continuous alternative can fit the contrast



B · Faint blue light limits the ratio



The blue band is faint. The box extraction allows zero blue light within its uncertainty, so its ratio has no finite upper 95% bound.

A: archive-rescaled 1σ errors; frozen bands and means shaded / colored. Dotted purple: hydrogen's limit, 3646 Å.

*The continuous model may bend at 3646 Å; it is an illustrative assumption, not a physical identification or proof that no edge exists.

B: bars are supplied diagonal 1σ errors for each estimator. All points reuse the same exposures; their spread is not a confidence interval.
